Steel

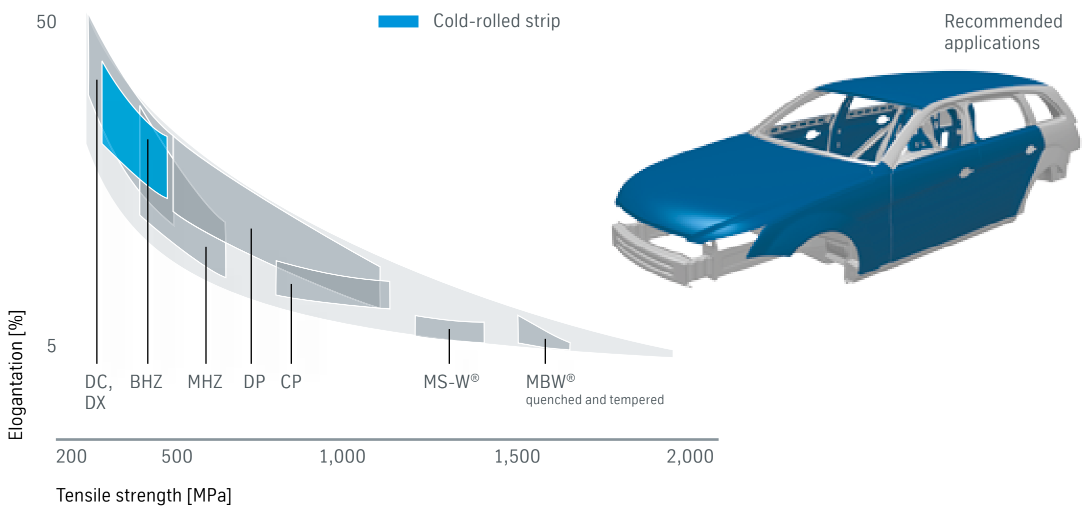
Bake-hardening steels BHZ

Product information

thyssenkrupp

Issue: May 2016, version 0

Overview of steel grades



Content

Areas of application

The particular advantage of bake-hardening steels is that they ensure good cold workability due to their relatively low yield point and good r and n values. The initial strength is adjusted with solid solutions. They achieve their final strength on the worked component during paint curing. Bake-hardening steels thus excellently reconcile conflicting requirements in terms of working behavior and component strength. Bake-hardening steels offer benefits for use in exterior bodywork parts – especially with only slightly worked components, which do not undergo any noticeable strengthening due to working – since the bake-hardening effect provides significantly improved buckling resistance and stiffness compared to other steels. The preferred applications include flat exterior skin parts such as roofs, hoods and door outer panels. Bake-hardening steels by thyssenkrupp are available on request for long-term corrosion protection in various high quality surface finishes.

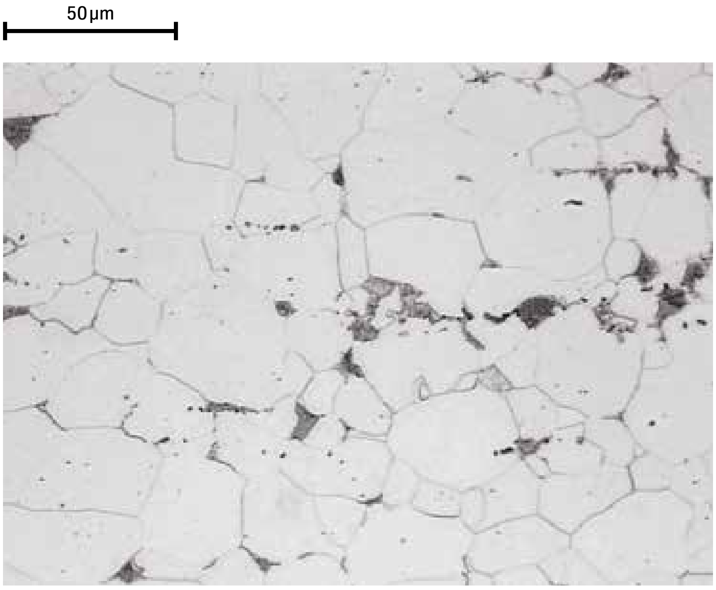
Material characteristics

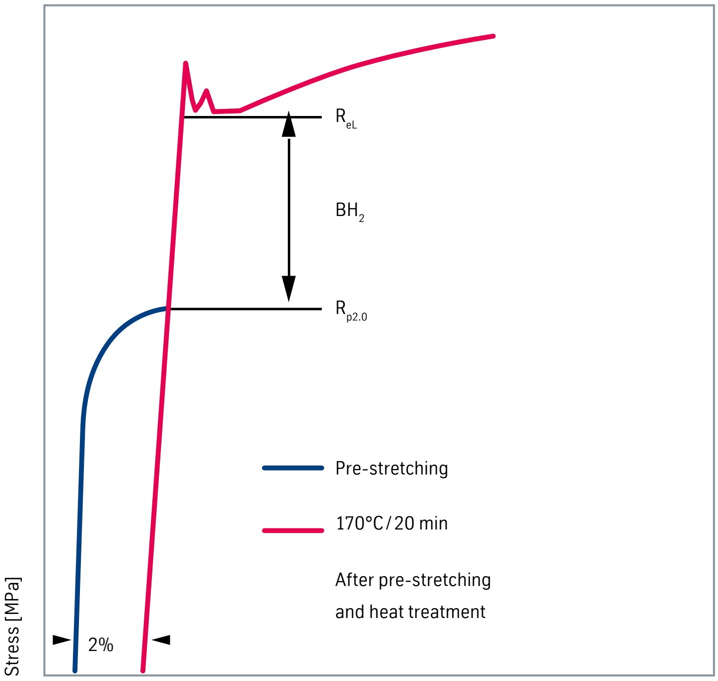
Bake-hardening steels by thyssenkrupp are resistant to aging at room temperature over a long period. Solid solution hardening elements such as P, Mn and Si are used to achieve the desired initial strength. A specifically chosen amount of dissolved carbon in the ferritic matrix causes an additional increase in the yield limit through controlled carbon aging during curing of the automobile paintwork in conjunction with prior deformation hardening (BH effect).

Micrograph of BHZ



The picture shows the typical microstructure of a bake-hardening steel after etching with nital, with perlite and isolated granular cementite in the ferritic matrix.

Determination of the bake-hardening value[1]



[1] As per DIN EN 10325 BH_2 after 2% stretching in a tensile test.

Notes on applications and processing

Forming

With bake-hardening steels, diffusion of the free carbon atoms, typically implemented by paint curing heat treatment of an automobile body, is used to increase the strength of the finished component. They have the great advantage that parts with only minor shape changes achieve an additional increase in strength through the downstream painting process. Bake-hardening steels are therefore particularly suitable for flat parts which are not heavily stretched. The choice of the right type for a given strength must also be made with a special focus on the actual anticipated forming stresses. This allows optimum leveraging of specific benefits so that the steels can also be used for difficult drawn parts.

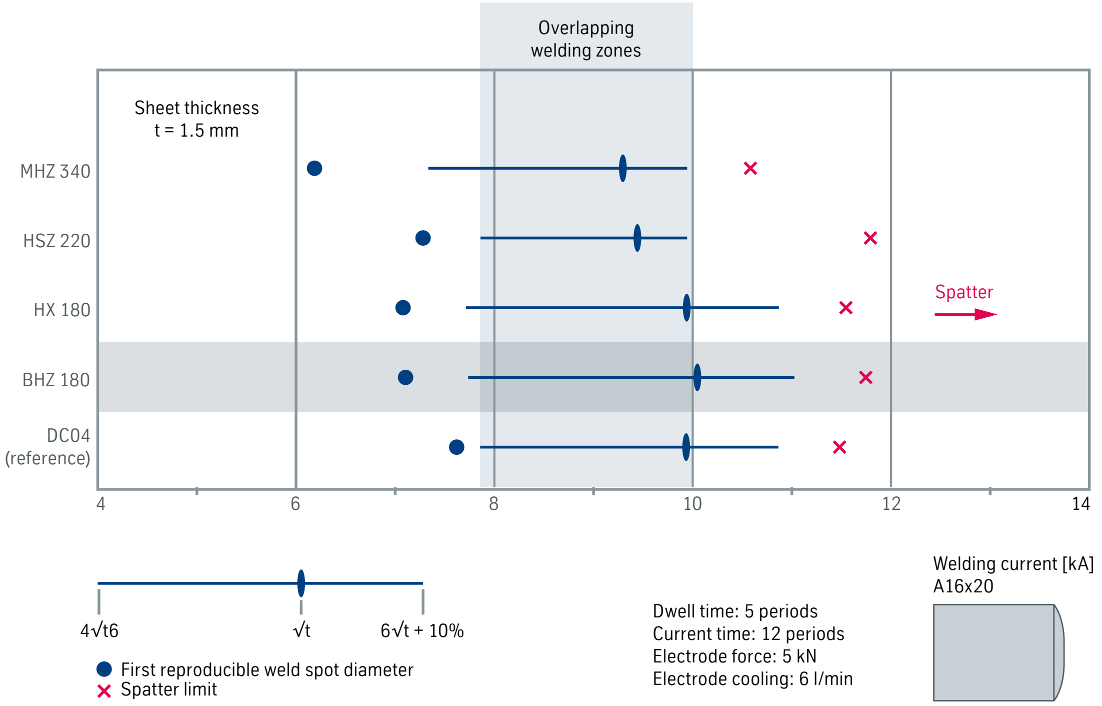
Processing instructions for joining

When it comes to joining bake-hardening steels, the processor can choose from a large number of joining processes. They are suitable for welding in both same-grade and hybrid joints with other common steel grades. The precondition is welding parameters matched to the material.

Resistance spot welding

The focus is traditionally on resistance spot welding, especially in car body manufacture. In particular, thin sheets with a thickness of less than 3 mm can be joined more economically and more reliably using this mass production process. However, doing so typically involves modifying the three welding parameters: welding current, welding time and electrode force. The influence of the electrode force and welding time on the welding zone is of central interest here. Higher electrode forces and longer welding times are normally required as the sheet thickness and strength increase, to ensure a sufficiently large welding zone. Similarly, the use of multi-pulse welding as per SEP 1220-2 can have a positive effect on the width of the welding zone. For zinc and zinc alloy coatings, the electrode forces, welding currents and welding times need to be increased compared to the non-alloyed base material to compensate for contraction of the welding zone due to the coating. The width of the welding zone does not only depend on the combination of sheet grade, surface and thickness; process parameters such as the current type and electrode geometry also play a significant role. The figure shows that the welding zones of BHZ steels are similar to those of other conventional high-strength steels in a comparable welding current range. In addition to good welding suitability of the individual steel grades, welding suitability is also assured for combinations of the various materials offered by the steel industry today for similar welding parameter settings.

Welding zones of conventional higher-strength and high-strength steels compared



Fatigue strength and crash performance

Higher-strength is assured for BHZ steels in addition to the specific deformation properties. As the yield strength and tensile strength increase, the fatigue limit and crash energy absorption capacity also increase. The bake-hardening effect further increases the yield strength values, which are particularly significant for strength analyses. The increased buckling strength is just one example.
